

Cryptography

Module 18

Unmask the Invisible Hacker.

Market Survey 2014: The Year of Encryption

60% of those surveyed said that Edward Snowden revelations have made them more aware of data security

Among the 60%, approximately **70%** have been directly influenced to look at new data security systems

94% of people looking to invest in new systems are specifically examining secure (encryption) electronic data security systems

Only **17%** of those surveyed said their existing secure information sharing system was easy to use

100% of those not interested in security systems admitted to regularly sharing sensitive/ confidential data with external third parties

Over **2/3** of people felt that government certification combined with ease of use would be deciding factors when selecting a data security solution

One in two people now perceive the Cloud to be less secure as result of Snowden

One third of those surveyed were not that upcoming EU DPA reforms would impact the way they or their organization handles and protects data

Case Study: Heartbleed

Heartbleed is a security flaw in the [OpenSSL](#) cryptographic software library, which allows data traversal over [SSL/TLS in plain-text](#)

Heartbleed exploits a built-in feature of OpenSSL called [heartbeat](#)

Attackers exploit this vulnerability to get information such as OpenSSL [private keys](#), OpenSSL [secondary keys](#), up to [64kb of memory](#) from the affected server, [usernames](#) and [passwords](#), etc.

Versions of OpenSSL affected by Heartbleed include [1.0.1](#) to [1.0.1f](#)

Updating OpenSSL to version [1.0.1g](#) or [higher](#) resolves the vulnerability

Case Study: Poodlebleed

- Poodlebleed (**Padding Oracle On Downgraded Legacy Encryption**) is a security vulnerability in the design of SSL 3.0
- Attacker exploits this vulnerability to **decrypt ciphertext in transit** between a server and a browser, by means of padding oracle side-channel attack
- **Countermeasures:**
 - Completely **disable SSL 3.0** on the client side and the server side
 - Implement **anti-POODLE record splitting**

Cryptography

CEH
Certified Ethical Hacker

01

Cryptography is the **conversion of data** into a scrambled code that is decrypted and sent across a private or public network

02

Cryptography is used to protect confidential data such as **email messages**, chat sessions, **web transactions**, personal data, **corporate data**, e-commerce applications, etc.

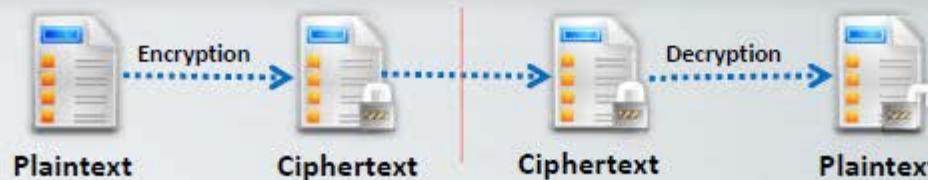

03

Objectives

- Confidentiality
- Integrity
- Authentication
- Non-repudiation

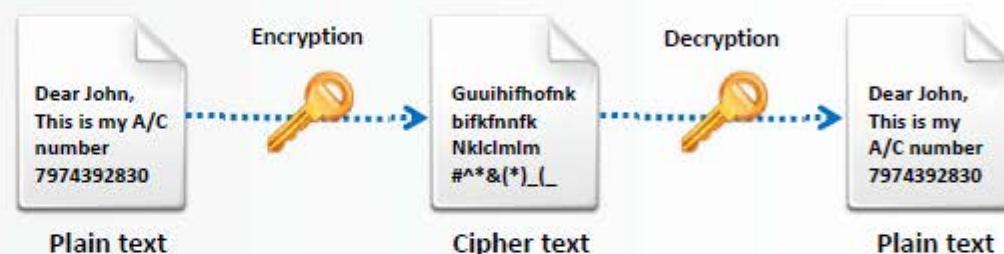

04

Types of Cryptography

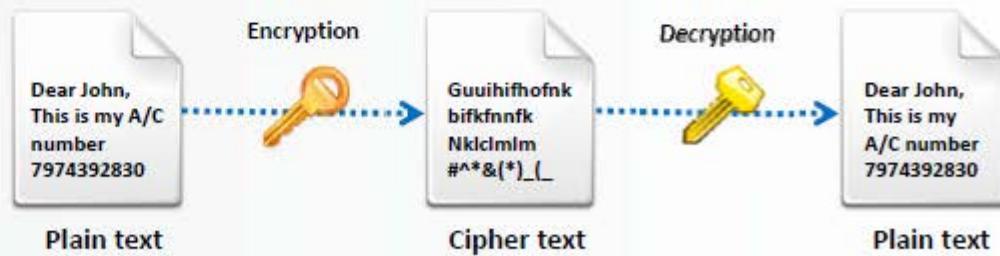

Symmetric Encryption

Symmetric encryption (secret-key, shared-key, and private-key) **uses the same key** for encryption as it does for decryption

Asymmetric Encryption

Asymmetric encryption (public-key) **uses different encryption keys** for encryption and decryption. These keys are known as public and private keys

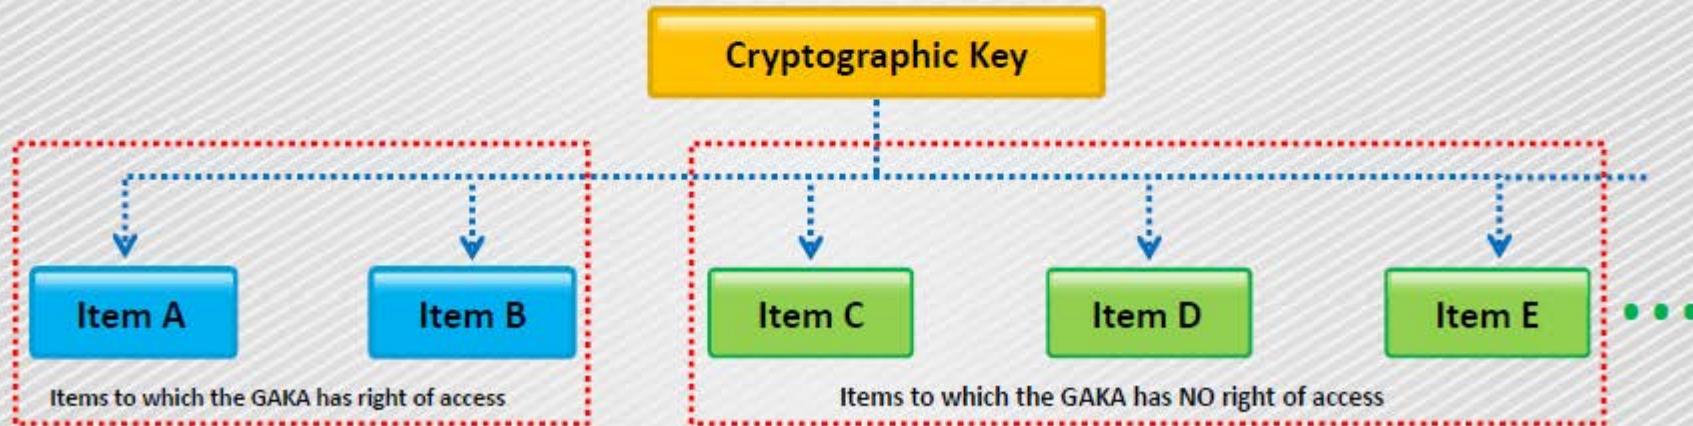

Government Access to Keys (GAK)

Government Access to Keys means that software companies will give **copies of all keys**, (or at least enough of the key that the remainder could be cracked) to the government

The government promises that they will hold on to the keys in a **secure way**, and will only use them when a **court issues a warrant** to do so

To the government, this issue is similar to the **ability to wiretap phones**

Ciphers

Ciphers are **algorithms** used to encrypt or decrypt the data

Modern Ciphers

Classical Ciphers

Substitution cipher

A block of plaintext is replaced with ciphertext

Transposition cipher

The letters of the plaintext are shifted about to form the cryptogram

Based on the type of key used

Private Key

Same key is used for encryption and decryption

Public Key

Two different keys are used for encryption and decryption

Based on the type of input data

Block Cipher

Encrypts block of data of fixed size

Stream Cipher

Encrypts continuous streams of data

Data Encryption Standard (DES)

CEH
Certified Ethical Hacker

The algorithm is designed to **encipher** and **decipher** blocks of data consisting of **64 bits** under control of a 56-bit key

DES is the **archetypal block cipher** — an algorithm that takes a fixed-length string of plaintext bits and transforms it into a ciphertext bitstring of the same length

Due to the **inherent weakness** of DES with today's technologies, some organizations repeat the process three times (3DES) for added strength, until they can afford to update their equipment to AES capabilities

Advanced Encryption Standard (AES)

AES is a **symmetric-key** algorithm for securing sensitive but unclassified material by U.S. government agencies

AES is an **iterated block cipher**, which works by repeating the same operation **multiple times**

It has a **128-bit** block size, with key sizes of **128, 192, and 256 bits**, respectively for AES-128, AES-192, and AES-256

AES Pseudocode

```
Cipher (byte in[4*Nb], byte out[4*Nb],  
word w[Nb*(Nr+1)])  
begin  
    byte state[4,Nb]  
    state = in  
    AddRoundKey(state, w)  
    for round = 1 step 1 to Nr-1  
        SubBytes(state)  
        ShiftRows(state)  
        MixColumns(state)  
        AddRoundKey(state, w+round*Nb)  
    end for  
    SubBytes(state)  
    ShiftRows(state)  
    AddRoundKey(state, w+Nr*Nb)  
    out = state  
end
```

RC4, RC5, RC6 Algorithms

RC4

A variable **key size stream cipher** with byte-oriented operations, and is based on the use of a random permutation

RC5

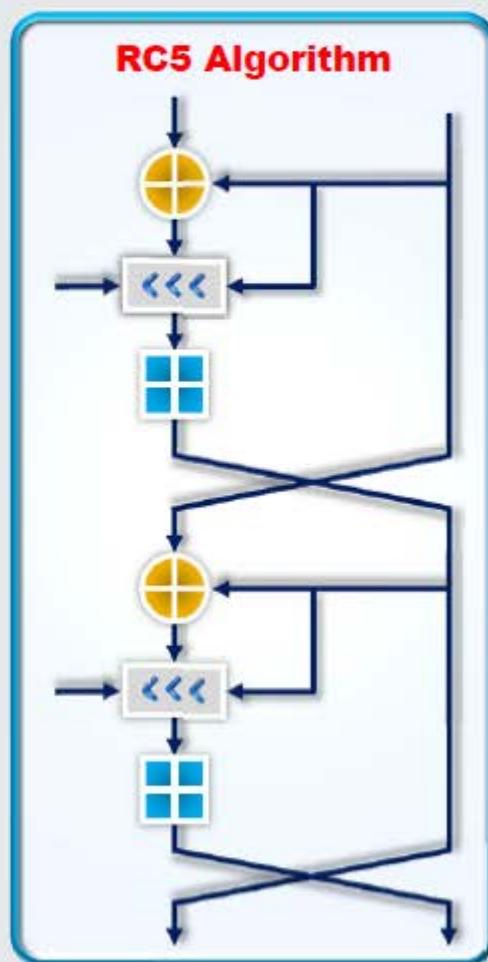

It is a **parameterized algorithm** with a variable block size, a variable key size, and a variable number of rounds. The key size is **128-bits**

RC6

RC6 is a **symmetric key block cipher** derived from RC5 with two additional features:

- Uses **Integer multiplication**
- Uses **four 4-bit working registers** (RC5 uses two 2-bit registers)

The DSA and Related Signature Schemes

C|EH
Certified Ethical Hacker

Digital Signature Algorithm

FIPS 186-2 specifies the Digital Signature Algorithm (DSA) that may be used in the **generation and verification of digital signatures** for sensitive, unclassified applications

Digital Signature

The digital signature is **computed using a set of rules** (i.e., the DSA) **and a set of parameters** such that the identity of the signatory and integrity of the data can be verified

Each entity creates a public key and corresponding private key

1. Select a prime number q such that $2^{159} < q < 2^{160}$
2. Choose t so that $0 \leq t \leq 8$
3. Select a prime number p such that $2^{511+64t} < p < 2^{512+64t}$ with the additional property that q divides $(p-1)$
4. Select a generator α of the unique cyclic group of order q in Z_p^*
5. To compute α , select an element g in Z_p^* and compute $g^{(p-1)/q} \bmod p$
6. If $\alpha = 1$, perform step five again with a different g
7. Select a random a such that $1 \leq a \leq q-1$
8. Compute $y = \alpha^a \bmod p$

The public key is (p, q, α, y) . The private key is a .

RSA (Rivest Shamir Adleman)

CEH
Certified Ethical Hacker

RSA is an **Internet encryption and authentication system** that uses an algorithm developed by Ron Rivest, Adi Shamir, and Leonard Adleman

01

RSA encryption is widely used and is one of the **de-facto encryption standard**

02

It uses **modular arithmetic** and **elementary number theories** to perform computations using two large prime numbers

03

The RSA Signature Scheme

C|EH
Certified Ethical Hacker

Algorithm Key generation for the RSA signature scheme

SUMMARY: each entity creates an RSA public key and a corresponding private key.
Each entity A should do the following:

1. Generate two large distinct random primes p and q , each roughly the same size.
2. Compute $n = pq$ and $\phi = (p - 1)(q - 1)$.
3. Select a random integer e , $1 < e < \phi$, such that $\gcd(e, \phi) = 1$.
4. Use the extended Euclidean algorithm (Algorithm 2.107) to compute the unique integer d , $1 < d < \phi$, such that $ed \equiv 1 \pmod{\phi}$.
5. A's public key is (n, e) ; A's private key is d .

Algorithm RSA signature generation and verification

SUMMARY: entity A signs a message $m \in \mathcal{M}$. Any entity B can verify A's signature and recover the message m from the signature.

1. *Signature generation.* Entity A should do the following:
 - (a) Compute $\tilde{m} = R(m)$, an integer in the range $[0, n - 1]$.
 - (b) Compute $s = \tilde{m}^d \pmod{n}$.
 - (c) A's signature for m is s .
2. *Verification.* To verify A's signature s and recover the message m , B should:
 - (a) Obtain A's authentic public key (n, e) .
 - (b) Compute $\tilde{m} = s^e \pmod{n}$.
 - (c) Verify that $\tilde{m} \in \mathcal{M}_R$; if not, reject the signature.
 - (d) Recover $m = R^{-1}(\tilde{m})$.

Example of RSA Algorithm

```
P = 61    <= first prime number (destroy this after computing E and D)
Q = 53    <= second prime number (destroy this after computing E and D)
PQ = 3233 <= modulus (give this to others)
E = 17    <= public exponent (give this to others)
D = 2753  <= private exponent (keep this secret!)

Your public key is (E,PQ).
Your private key is D.
```

The encryption function is: $\text{encrypt}(T) = (T^E) \bmod PQ$
 $= (T^{17}) \bmod 3233$

The decryption function is: $\text{decrypt}(C) = (C^D) \bmod PQ$
 $= (C^{2753}) \bmod 3233$

To encrypt the plaintext value 123, do this:

```
encrypt(123) = (123^17) mod 3233
                = 337587917446653715596592958817679803 mod 3233
                = 855
```

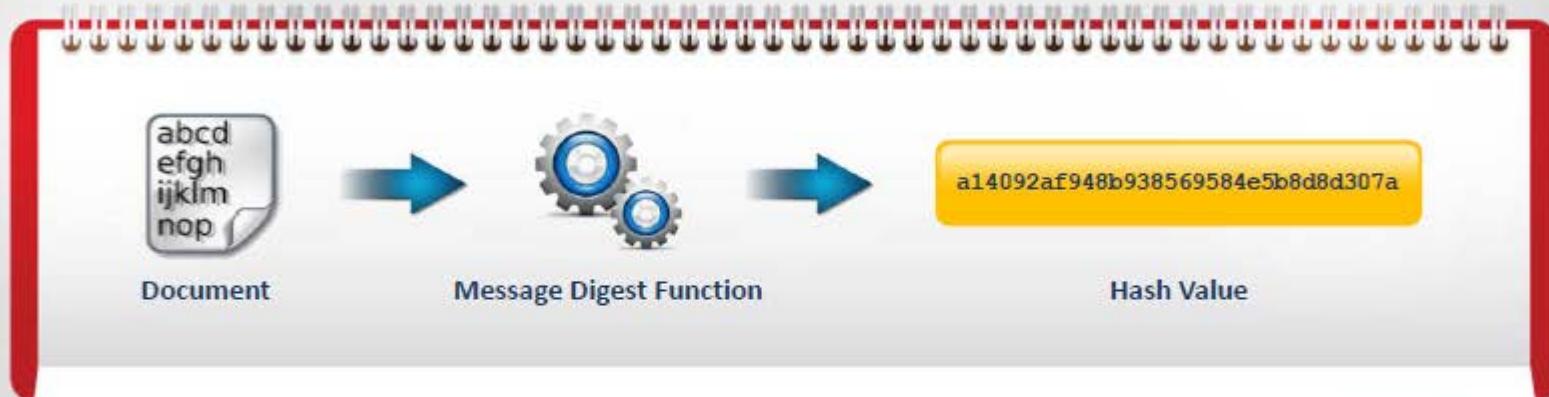

To decrypt the cipher text value 855, do this:

```
decrypt(855) = (855*2753) mod 3233
                = 123
```

Message Digest (One-way Hash) Functions

CEH
Certified Ethical Hacker

Hash functions **calculate a unique fixed-size bit string** representation called a message digest of any arbitrary block of information

If any given bit of the function's input is changed, every output bit has a **50 percent** chance of changing

It is computationally infeasible to have two files with the **same message digest value**

Note: Message digests are also called one-way hash functions because they cannot be reversed

Message Digest Function: MD5

C|EH
Certified Ethical Hacker

MD5 Algorithm

MD5 algorithm takes a message of arbitrary length as input and outputs a 128-bit fingerprint or message digest of the input

MD5 hash is a 32-digit hexadecimal number

MD5 is not collision resistant, use of latest algorithms such as SHA-2 and SHA-3 is recommended

It is still deployed for digital signature applications, file integrity checking and storing passwords

Quick Checksum Verifier

<http://www.bitdreamers.com>

Secure Hashing Algorithm (SHA)

It is an algorithm for generating cryptographically secure one-way hash, published by the **National Institute of Standards and Technology** as a **U.S. Federal Information Processing Standard**

SHA1

It produces a **160-bit digest** from a message with a maximum length of **(2⁶⁴ – 1) bits**, and resembles the MD5 algorithm

SHA2

It is a family of two similar hash functions, with different block sizes, namely **SHA-256** that uses **32-bit words** and **SHA-512** that uses **64-bit words**

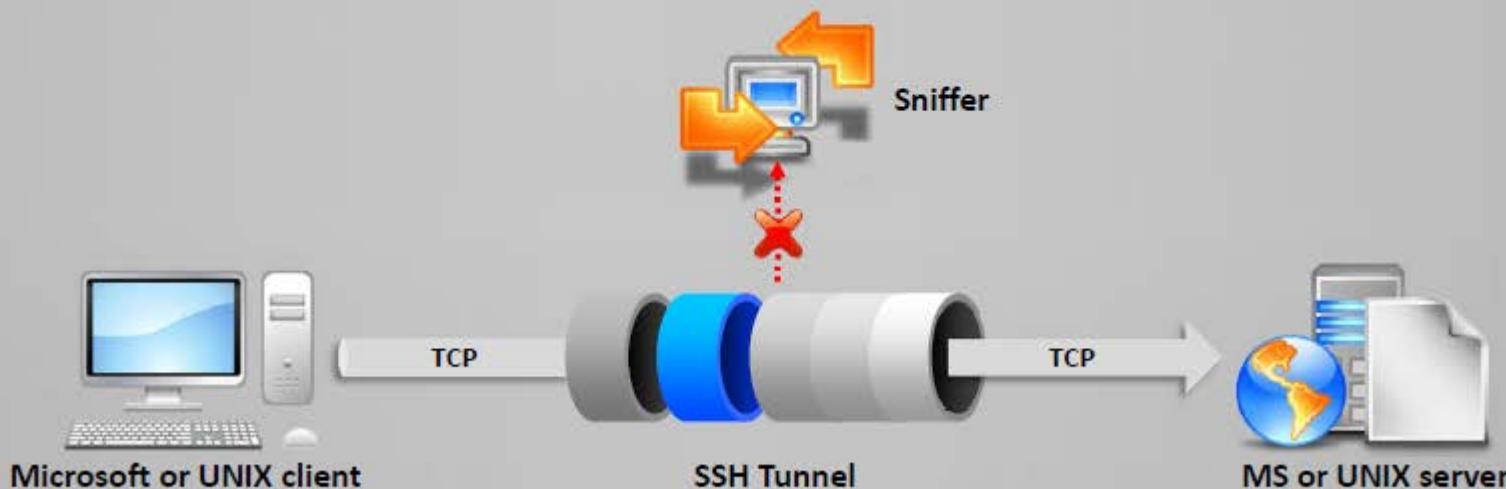

SHA3

SHA-3 uses the **sponge construction** in which message blocks are **XORed** into the initial bits of the state, which is then invertibly permuted

What is SSH (Secure Shell)?

CEH
Certified Ethical Hacker

- 1 SSH is a secure replacement for **telnet** and the **Berkeley remote-utilities** (rlogin, rsh, rcp, and rdist)
- 2 It provides an **encrypted channel** for remote logging, command execution and file transfers
- 3 Provides strong **host-to-host and user authentication**, and secure communication over an insecure Internet

Note: SSH2 is a more secure, efficient, and portable version of SSH that includes SFTP, an SSH2 tunneled FTP

Public Key Infrastructure (PKI)

Public Key Infrastructure (PKI) is a **set of hardware, software, people, policies, and procedures** required to create, manage, distribute, use, store, and revoke **digital certificates**

Components of PKI

1

Certificate Management System

Generates, distributes, stores, and verifies certificates

2

Digital Certificates

Establishes credentials of a person when doing online transactions

3

Validation Authority (VA)

Stores certificates (with their public keys)

4

Certificate Authority (CA)

Issues and verifies digital certificates

5

End User

Requests, manages, and uses certificates

6

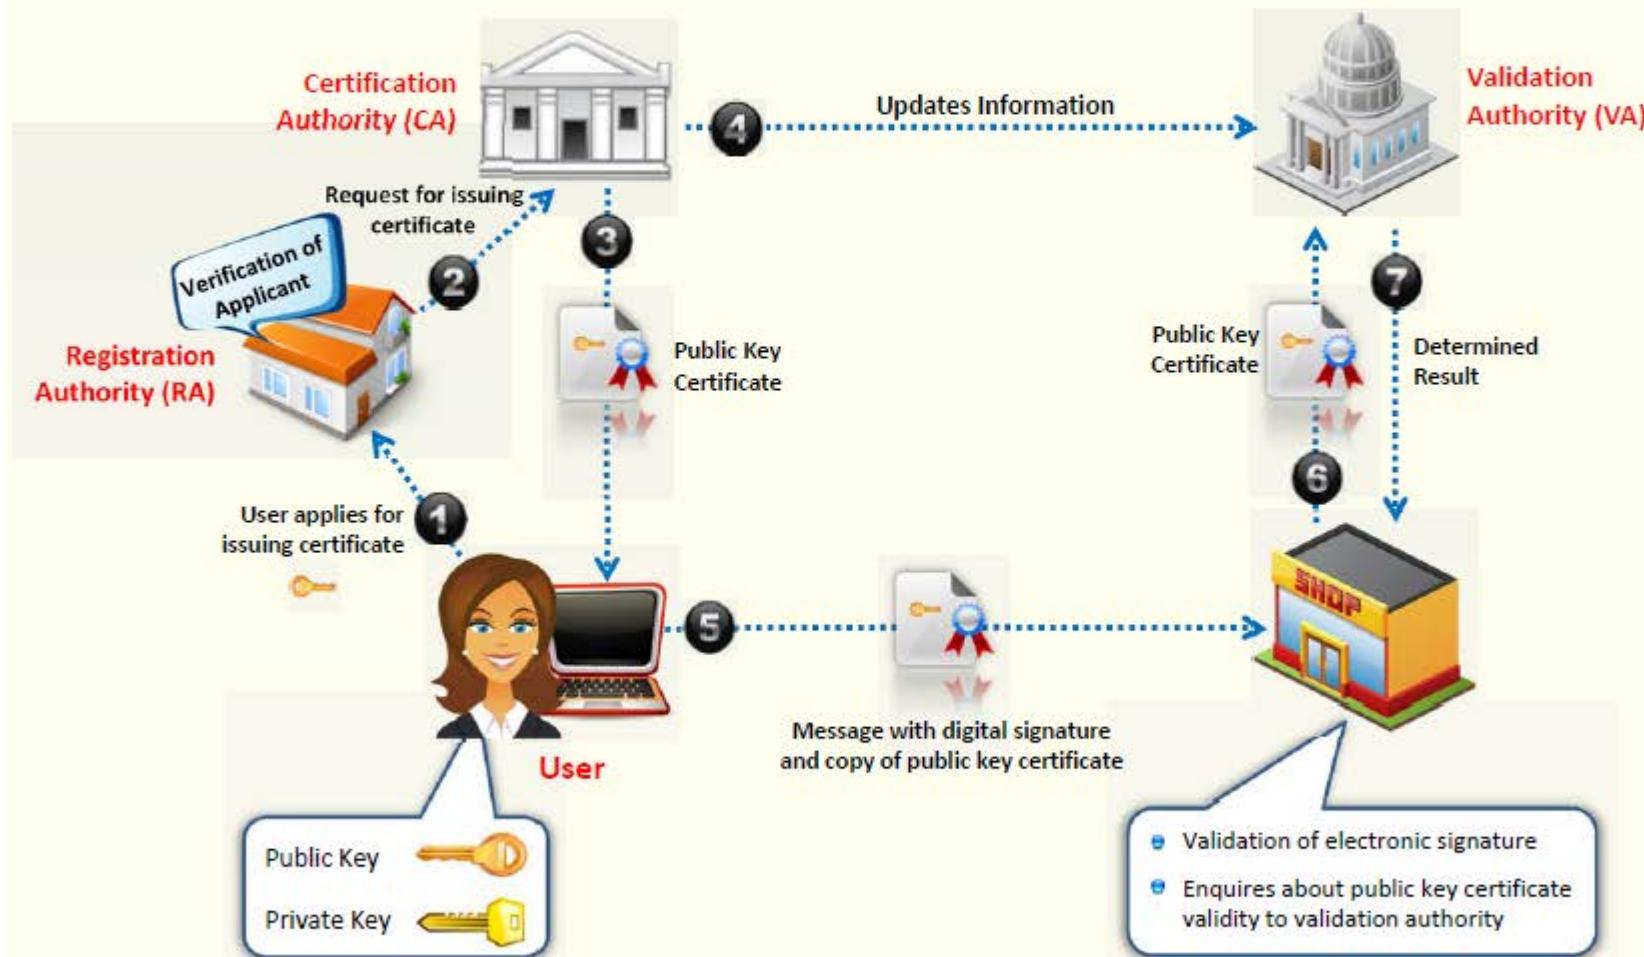

Registration Authority (RA)

Acts as the verifier for the certificate authority

Public Key Infrastructure (PKI)

(Cont'd)

CEH
Certified Ethical Hacker

Signed Certificate (CA) Vs. Self Signed Certificate

CEH
Certified Ethical Hacker

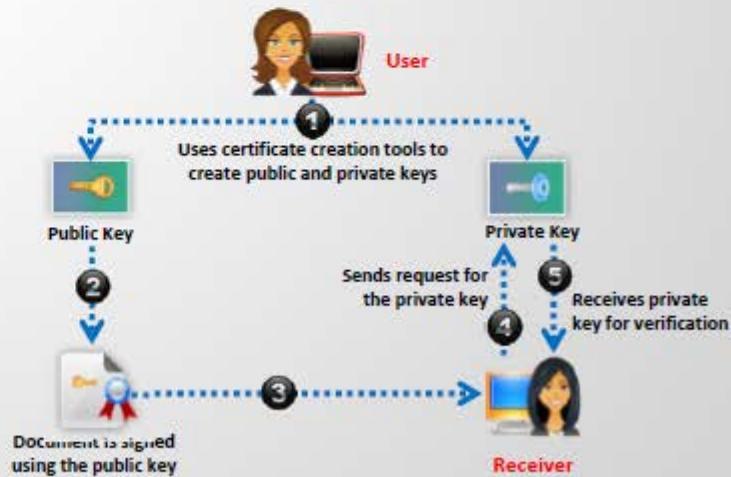

Signed Certificate

- User approaches a trustworthy **Certification Authority (CA)** and purchases digital certificate
- User gets the **public key** from the CA, he signs the document using it
- The signed document is delivered to the receiver
- The receiver can verify the certificate by enquiring in **Validation Authority (VA)**
- VA verifies the certificate to the receiver but it does not share private key

Self-signed Certificate

- User creates public and private keys using a tool such as **Adobe Reader**, **Java's keytool**, **Apple's Keychain**, etc.
- User uses public key to **sign the document**
- The **self-signed document** is delivered to the receiver
- The receiver request the user for his **private key**
- User **shares the private key** with the receiver

Digital Signature

1
2

Digital signature used asymmetric cryptography to simulate the security properties of a **signature in digital, rather than written form**

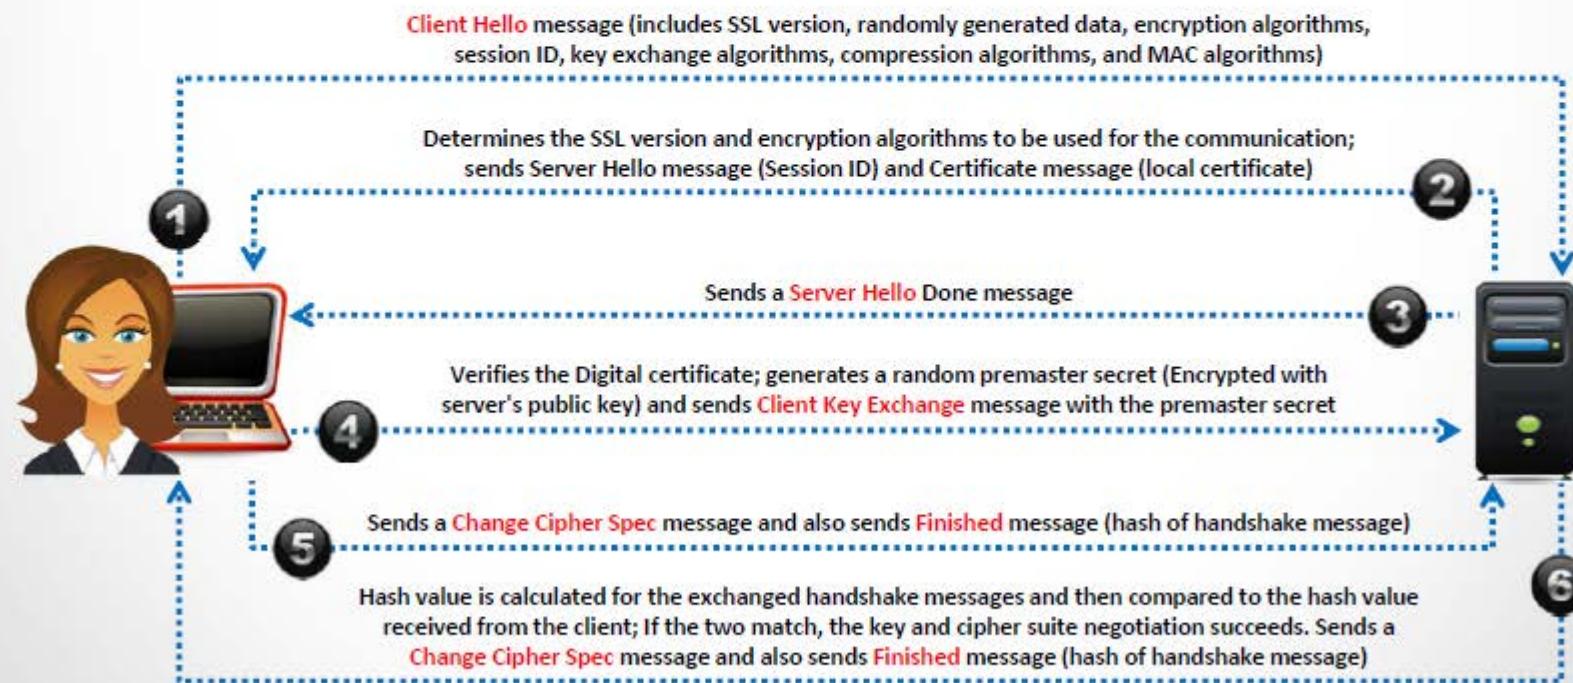

A digital signature may be further protected, by **encrypting the signed email** for confidentiality

SSL (Secure Sockets Layer)

CEH
Certified Ethical Hacker

- SSL is an application layer protocol developed by Netscape for **managing the security** of a message transmission on the Internet
- It uses **RSA asymmetric (public key) encryption** to encrypt data transferred over SSL connections

Transport Layer Security (TLS)

CEH
Certified Ethical Hacker

- TLS is a protocol **to establish a secure connection** between a client and a server and ensure privacy and integrity of information during transmission
- It uses the RSA algorithm with 1024 and 2048 bit strengths

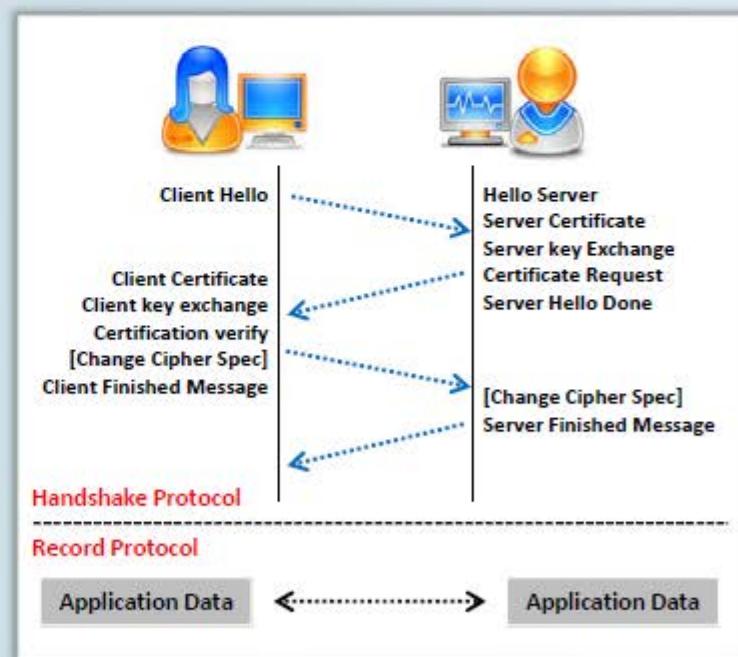

TLS Handshake Protocol

It allows the client and server to authenticate each other, select encryption algorithm, and exchange symmetric key prior to data exchange

TLS Record Protocol

It provides secured connections with an encryption method such as Data Encryption Standard (DES)

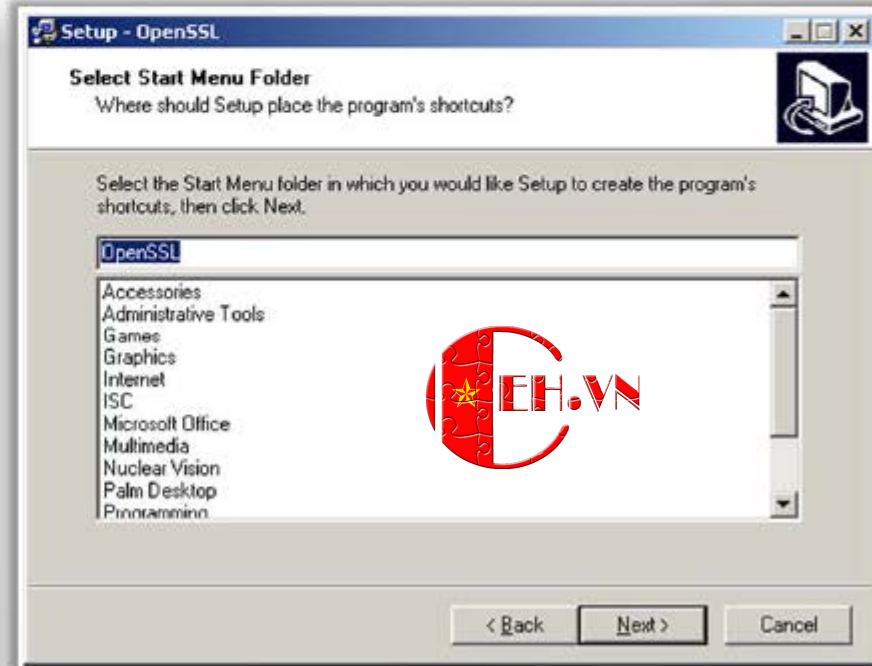

Cryptography Toolkit: OpenSSL

- OpenSSL is an open source cryptography toolkit implementing the **Secure Sockets Layer (SSL v2/v3)** and **Transport Layer Security (TLS v1)** network protocols and related cryptography standards required by them
- The openssl program is a command line tool for using the various **cryptography functions** of OpenSSL's crypto library from the shell

OpenSSL can be used for:

- Creation and management of private keys, public keys and parameters
- Public key cryptographic operations
- Creation of X.509 certificates, CSRs and CRLs
- Calculation of Message Digests
- Encryption and Decryption with Ciphers
- SSL/TLS Client and Server Tests
- Handling of S/MIME signed or encrypted mail
- Time Stamp requests, generation and verification

Cryptography Toolkit: Keyczar

CEH
Certified Ethical Hacker

- Keyczar is an open source cryptographic toolkit designed to make it easier and safer for developers to use **cryptography in their applications**
- It **supports authentication** and **encryption** with both symmetric and asymmetric keys

<http://www.keyczar.org>

Features

- Key rotation and versioning
- Safe default algorithms, modes, and key lengths
- Automated generation of initialization vectors and ciphertext signatures
- Java, Python, and C++ implementations
- International support in Java

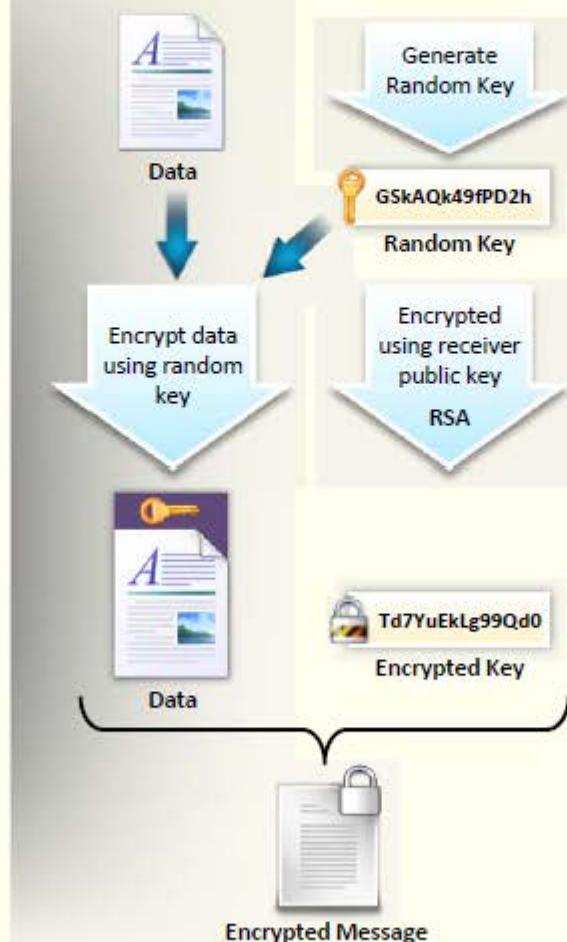

Pretty Good Privacy (PGP)

CEH
Certified Ethical Hacker

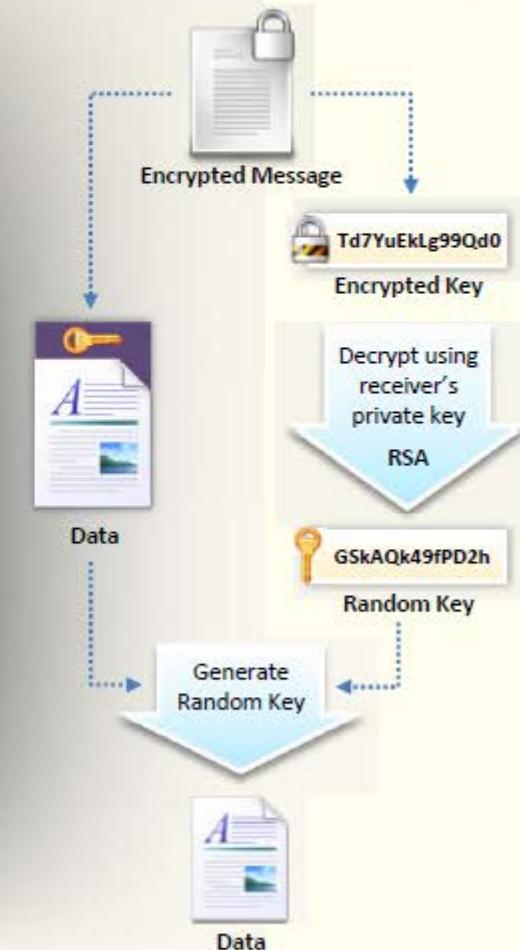

Pretty Good Privacy

- PGP (Pretty Good Privacy) is a protocol used to **encrypt** and **decrypt** data that provides **authentication** and **cryptographic privacy**
- PGP is often used for data **compression**, **digital signing**, encryption and decryption of **messages**, **emails**, **files**, **directories**, and to enhance privacy of email communications
- PGP combines the best features of both **conventional** and **public key cryptography** and is therefore known as **hybrid cryptosystem**

Disk Encryption

C|EH
Certified Ethical Hacker

01

Confidentiality

Disk encryption protects **confidentiality of the data** stored on disk by converting it into an unreadable code using disk encryption software or hardware

- Privacy
- Passphrase
- Hidden Volumes

02

Encryption

Disk encryption works in a similar way as **text message encryption** and protects data even when the OS not active

- Volume Encryption

03

Protection

With the use of an encryption program for your disk, you can **safeguard any information** to burn onto the disk, and keep it from falling into the wrong hands

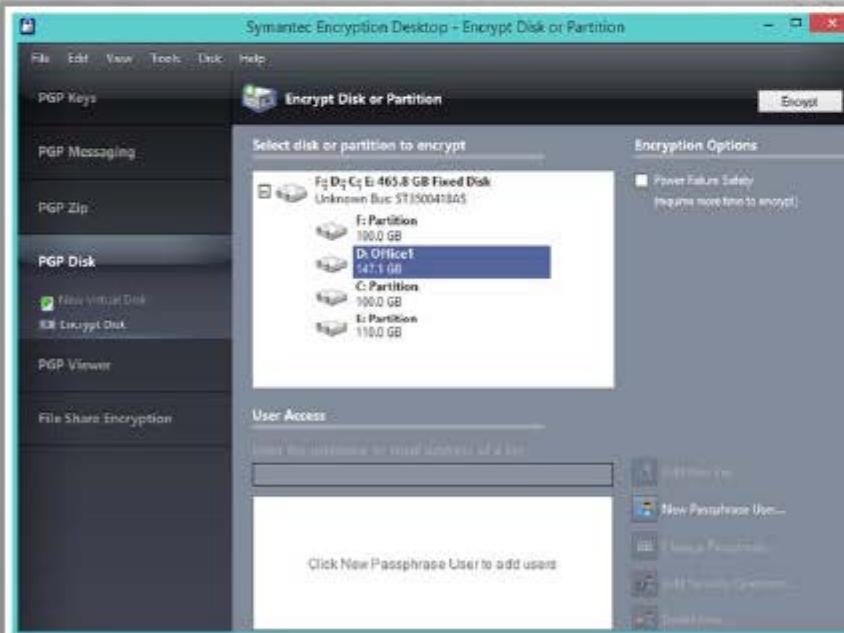

- Blue Ray
- DVD
- Backup

Disk Encryption Tools: Symantec Drive Encryption and GiliSoft Full Disk Encryption

CEH
Certified Ethical Hacker

Symantec Drive Encryption

- Symantec Drive Encryption provides **full disk encryption** for all data (user files, swap files, system files, hidden files, etc.) on desktops, laptops, and removable media
- It protects data from **unauthorized access**

<http://www.symantec.com>

GiliSoft Full Disk Encryption

- GiliSoft Full Disk Encryption offers encryption of all **disk partitions**, including the system partition
- It **provides automatic security** for all information on endpoint hard drives, including user data, operating system files and temporary and erased files

Cryptography Attacks

CEH
Certified Ethical Hacker

- Cryptography attacks are based on the assumption that the cryptanalyst has access to the **encrypted information**

Ciphertext-only attack

Known-plaintext attack

Chosen-plaintext

Chosen - ciphertext attack

Chosen-key attack

Adaptive chosen-plaintext attack

Timing attack

Rubber hose attack

Cryptography Attacks

(Cont'd)

Ciphertext-only Attack

Attacker has access to the cipher text; goal of this attack to **recover encryption key** from the ciphertext

Adaptive Chosen-plaintext Attack

Attacker makes a **series of interactive queries**, choosing subsequent plaintexts based on the information from the previous encryptions

Chosen-plaintext Attack

Attacker **defines his own plaintext**, feeds it into the cipher, and analyzes the resulting ciphertext

Known-plaintext Attack

Attacker has **knowledge of some part of the plain text**; using this information the key used to generate ciphertext is deduced so as to decipher other messages

Cryptography Attacks

(Cont'd)

Chosen-ciphertext Attack

Attacker obtains the plaintexts corresponding to an **arbitrary set** of ciphertexts of his own choosing

Chosen-key Attack

A **generalization** of the chosen-text attack

It is based on repeatedly measuring the **exact execution times** of modular exponentiation operations

Rubber Hose Attack

Timing Attack

Code Breaking Methodologies

C|EH
Certified Ethical Hacker

Trickery
and Deceit

It involves the use of **social engineering techniques** to extract cryptography keys

Brute-Force

Cryptography keys are discovered by **trying every possible combination**

One-Time
Pad

A one-time pad contains many **non-repeating groups of letters** or number keys, which are chosen randomly

Frequency
Analysis

- It is the study of the frequency of letters or groups of letters in a **ciphertext**
- It works on the fact that, in any given stretch of written language, certain letters and **combinations of letters** occur with varying frequencies

Brute-Force Attack

Attack Scheme

Defeating a cryptographic scheme by **trying a large number of possible keys** until the correct encryption key is discovered

Brute-Force Attack

Brute-force attack is a **high resource and time intensive process**, however, more certain to achieve results

Success Factors

Success of brute force attack depends on **length of the key, time constraint**, and **system security mechanisms**

Power/Cost	40 bits (5 char)	56 bit (7 char)	64 bit (8 char)	128 bit (16 char)
\$ 2K (1 PC. Can be achieved by an individual)	1.4 min	73 days	50 years	10^{20} years
\$ 100K (this can be achieved by a company)	2 sec	35 hours	1 year	10^{19} years
\$ 1M (Achieved by a huge organization or a state)	0.2 sec	3.5 hours	37 days	10^{18} years

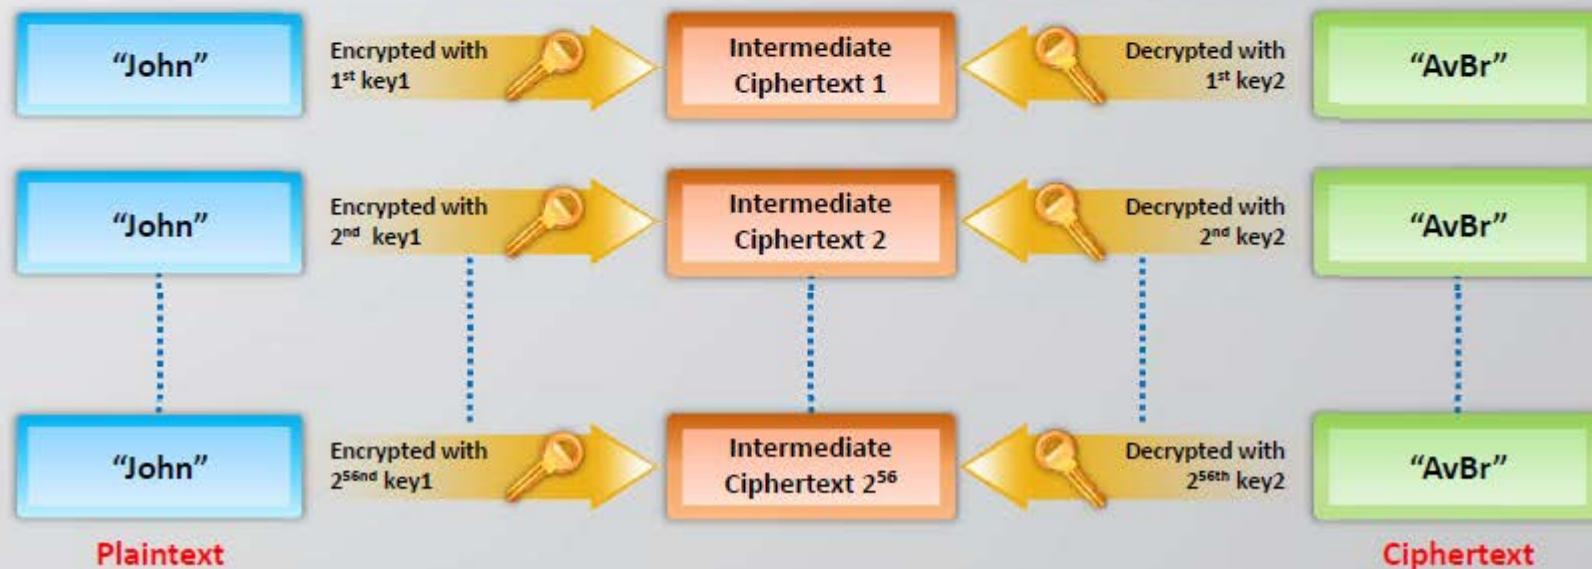

Estimate Time for Successful Brute-force Attack

Meet-in-the-Middle Attack on Digital Signature Schemes

CEH
Certified Ethical Hacker

- The attack works by **encrypting from one end and decrypting from the other end**, thus meeting in the middle
- It can be used for **forging signatures** even on digital signatures that use multiple-encryption scheme

Side Channel Attack

01

Side channel attack is a **physical attack** performed on a cryptographic device/ cryptosystem to gain sensitive information

02

Cryptography is generally **implemented in hardware or software** which runs on physical devices such as semi-conductors

03

These semi-conductor devices include **resistor, transistor** and so on

04

These physical devices are affected by various **environmental factors** that include: power consumption, electro-magnetic field, light emission, timing and delay, and sound

05

In Side Channel attack, an attacker **monitors these channels (environmental factors)** and try to acquire the information useful for cryptanalysis

06

The information collected in this process is termed as **side channel information**

07

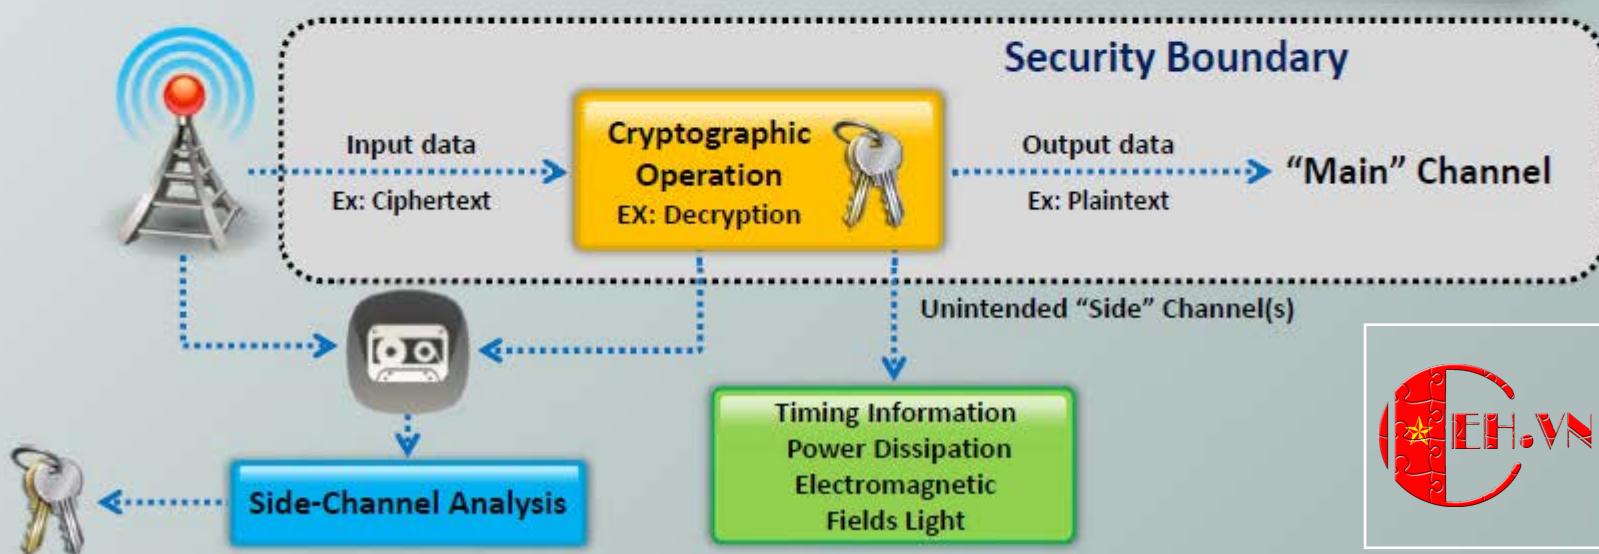

Side Channel Attacks (SCA) are **no way related to traditional/ theoretical form of attacks** like brute force attack

08

The concept of SCA is **based on the way, the cryptographic algorithms are implemented**, rather than at the algorithm itself

Side Channel Attack - Scenario

- Assume that an encrypted data is to be decrypted and displayed a plain text, inside a **trusted zone**
- At the time of decryption in a cryptosystem, **physical environmental factors** such as timing, power dissipation etc., acting on the components of a computer are recorded by an attacker
- The attacker analyzes this information in an attempt **to gain useful information** for cryptanalysis

Module Summary

- ❑ Cryptography is the conversion of data into a scrambled code that is decrypted and sent across a private or public network
- ❑ Symmetric encryption uses the same key for encryption as it does for decryption and asymmetric encryption uses different encryption keys for encryption and decryption
- ❑ Ciphers are algorithms used to encrypt or decrypt the data
- ❑ Hash functions calculate a unique fixed-size bit string representation called a message digest of any arbitrary block of information
- ❑ Public Key Infrastructure (PKI) is a set of hardware, software, people, policies, and procedures required to create, manage, distribute, use, store, and revoke digital certificates
- ❑ Digital signature used asymmetric cryptography to simulate the security properties of a signature in digital, rather than written form
- ❑ Disk encryption protects confidentiality of the data stored on disk by converting it into an unreadable code using disk encryption software or hardware
- ❑ Cryptography attacks are based on the assumption that the cryptanalyst has access to the encrypted information
